

Consider a stochastic discrete-time system described by the following stochastic difference equation:

$$\mathbf{x}_{k+1} = F(\mathbf{x}_k, \mathbf{u}(\mathbf{x}_k)) + \mathbf{w}_k \quad (1)$$

where $\mathbf{x}_k \in \mathbb{R}^n$ is the state of the system at time step k and $\mathbf{u}(\mathbf{x}_k) \in U$ is the control taken at time step k . Define $\mathbf{w} \sim \mathcal{N}_n(\mathbf{0}, \Sigma)$ to be the stochasticity in the environment where Σ is a diagonal matrix with entries $\sigma_1^2, \dots, \sigma_n^2$ along the diagonal. Define $\boldsymbol{\sigma}$ to be the vector such that $\text{Diag}(\boldsymbol{\sigma}) = \Sigma$. Define the hyper rectangle $\Omega_1 = \{\mathbf{v} \in \mathbb{R}^n \mid -6\boldsymbol{\sigma} \leq \mathbf{v} \leq 6\boldsymbol{\sigma}\}$ and define $\Omega_2 = \Omega \setminus \Omega_1$. Define $h(\mathbf{x})$ to be the barrier function for which $h(\mathbf{x}) \geq \mathbf{m}$. Then clearly:

$$\begin{aligned} \mathbb{E}[h(F(\mathbf{x}, \mathbf{u}) + \mathbf{w})] &= \int_{\Omega} h(F(\mathbf{x}, \mathbf{u}) + \mathbf{w})p(\mathbf{w}) d\mathbf{w} \\ &= \int_{\Omega_1} h(F(\mathbf{x}, \mathbf{u}) + \mathbf{w})p(\mathbf{w}) d\mathbf{w} + \int_{\Omega_2} h(F(\mathbf{x}, \mathbf{u}) + \mathbf{w})p(\mathbf{w}) d\mathbf{w} \end{aligned} \quad (2)$$

Now let W_i be hyper rectangles that form a partition over Ω_1 such that $\bigcup_{i \in I} W_i = \Omega_1$ and let U_i form a partition over U such that $\bigcup_{j \in J} U_j = U$. Then given that there exist matrices A_i and vectors \mathbf{b}_i such that for each $\mathbf{w}_i \in W_i$ the following inequality holds:

$$h(F(\mathbf{x}, \mathbf{u}) + \mathbf{w}) \geq A_i \begin{bmatrix} \mathbf{x} \\ \mathbf{u} \\ \mathbf{w}_i \end{bmatrix} + \mathbf{b}_i \quad (3)$$

Define

$$A_i = \begin{bmatrix} A_i^x & A_i^u & A_i^w \end{bmatrix}. \quad (4)$$

Then the integral can be bounded as such:

$$\begin{aligned} \int_{\Omega_1} h(F(\mathbf{x}, \mathbf{u}) + \mathbf{w})p(\mathbf{w}) d\mathbf{w} &\geq \sum_{i \in I} \int_{W_i} \left(\begin{bmatrix} A_i^x & A_i^u & A_i^w \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ \mathbf{u} \\ \mathbf{w}_i \end{bmatrix} + \mathbf{b}_i \right) p(\mathbf{w}_i) d\mathbf{w}_i \\ &= \sum_{i \in I} \left((A_i^x \mathbf{x} + A_i^u \mathbf{u} + \mathbf{b}_i) \int_{W_i} p(\mathbf{w}_i) d\mathbf{w}_i + A_i^w \int_{W_i} \mathbf{w}_i p(\mathbf{w}_i) d\mathbf{w}_i \right) \\ &= \sum_{i \in I} (A_i^x \mathbf{x} + A_i^u \mathbf{u} + \mathbf{b}_i) \mathbb{P}(\mathbf{w} \in W_i) + \sum_{i \in I} A_i^w \mathbb{E}[\mathbf{w} | \mathbf{w} \in W_i] \mathbb{P}(\mathbf{w} \in W_i) \end{aligned} \quad (5)$$

Additionally since $h(\mathbf{x}) \geq \mathbf{m}$:

$$\begin{aligned} \int_{\Omega_2} h(F(\mathbf{x}, \mathbf{u}) + \mathbf{w})p(\mathbf{w}) d\mathbf{w} &\geq \mathbf{m} \int_{\Omega_2} p(\mathbf{w}) d\mathbf{w} \\ &= \mathbf{m} \mathbb{P}(\mathbf{w} \in \Omega_2). \end{aligned} \quad (6)$$

Using (5) with (6) a lower bound can be obtained on (2) which is linear in \mathbf{u} and thus can be used for a quadratic programming problem.
